

Additional documentation: assumptions, reflections and limitations

Quratul N.O Thaher, September 2026

Assumptions and method

Penetration counts distinct homepasses. Open-access homes carry one row per competing ServCo, so count(distinct homeid) is used for network-level metrics. ServCo-level metrics use each ServCo's own reported active flag.

Minimum guarantee. Recorded as 0,25 for ServCo 101 and read as a guaranteed minimum penetration of 25% across XLS's addressable homepasses. Reading it as a share of revenue changes the calculation but not the conclusion: XLS exceeds the floor on either basis.

Media opportunity is a benchmark, not a forecast. Rp 1,184,059 is the margin captured if every region reached Jakarta Pusat's 53.5% attach rate, assuming each region's average add-on margin holds for new subscribers and excluding acquisition cost.

Sample scope. 1,000 homepasses, 20 fibernodes, 12 monthly snapshots (January to December 2025).

Reflections and limitations

The duplicate records required a judgment call, not a fix. 3,150 home-months carry two rows. These turned out to be open-access competition rather than data corruption, which is legitimate, since multiple ServCos can address the same home. But 547 show both ServCos simultaneously active, which is not physically possible.

Several findings are directional rather than causal. Activations more than doubled on affected nodes after 30 June, but 169 homepasses also entered the base that month, so part of the gain is new inventory rather than competitive effect.

A single reference month. Most cross-sectional analysis uses December 2025. Where a monthly series was available it was used.

Recommendation to improve the data

1. **Enforce a uniqueness constraint on active subscriptions per homepass.** The 547 conflicting records indicate no such constraint exists. Until it does, any activation count requires manual reconciliation.
